Connecting to a TapeTrack Framework Server

Each TapeTrack Framework Server accepts incoming communications on a single TCP/IP port (by default this port is 5000).

These incoming communications are firstly compressed with gzip level 9 compression, and then encrypted with AES 256 bit encryption.

To allow these connections the TapeTrack Framework Server must have firewall access to accept incoming connections, and the connecting clients must have outbound firewall access to establish a single TCP/IP stateful connection.

In the event the connection is terminated, either by a connection fault or the server timing out the connection, a new connection must be established.

In addition to direct TCP/IP connections, the TapeTrack communications API also supports connections via a HTTP Proxy.
